

DATA VORTEX — ROUND 1 PHASE 2

Phase 2 Insight Report

Selected questions: E3 (Easy), M1 (Medium), H6 (Hard)

1. Platform Engagement — E3

The platform with the highest average total engagement is **YouTube**, with an average total engagement of **4048.88**.

The SQL output shows that platform-level average engagement values are relatively close to one another. Therefore, platform choice does not appear to create a large difference in average engagement within this recovered dataset.

2. Location Engagement — M1

The highest-total-engagement location in the SQL output is **Los Angeles, USA**, with **1522219** total engagement across **379** posts with known engagement.

This analysis demonstrates that engagement can vary substantially across user locations. The result is based on total engagement, so both posting volume and engagement per post can influence the ranking.

3. Suspicious High-Impact Users — H6

The H6 query identified **95** users who satisfy all three specified conditions: fewer than 10,000 followers, average post engagement above the overall average, and at least one post where shares exceed likes.

These users are noteworthy because their engagement performance is high relative to the overall dataset despite having comparatively small follower counts. The shares-greater-than-likes condition adds a behavioral signal to the identification criteria.

4. Data Integrity

The SQL database contains 1,500 users and 12,000 cleaned posts. Database loading validation found zero invalid user references and zero duplicate post IDs. Missing engagement is excluded from engagement calculations rather than being interpreted as zero.

5. Limitations

The findings describe the recovered Dataset 01 only. They should not be generalized beyond this dataset. The analyses identify patterns and associations rather than proving causation. Records with incomplete engagement are intentionally excluded from engagement-based calculations.
